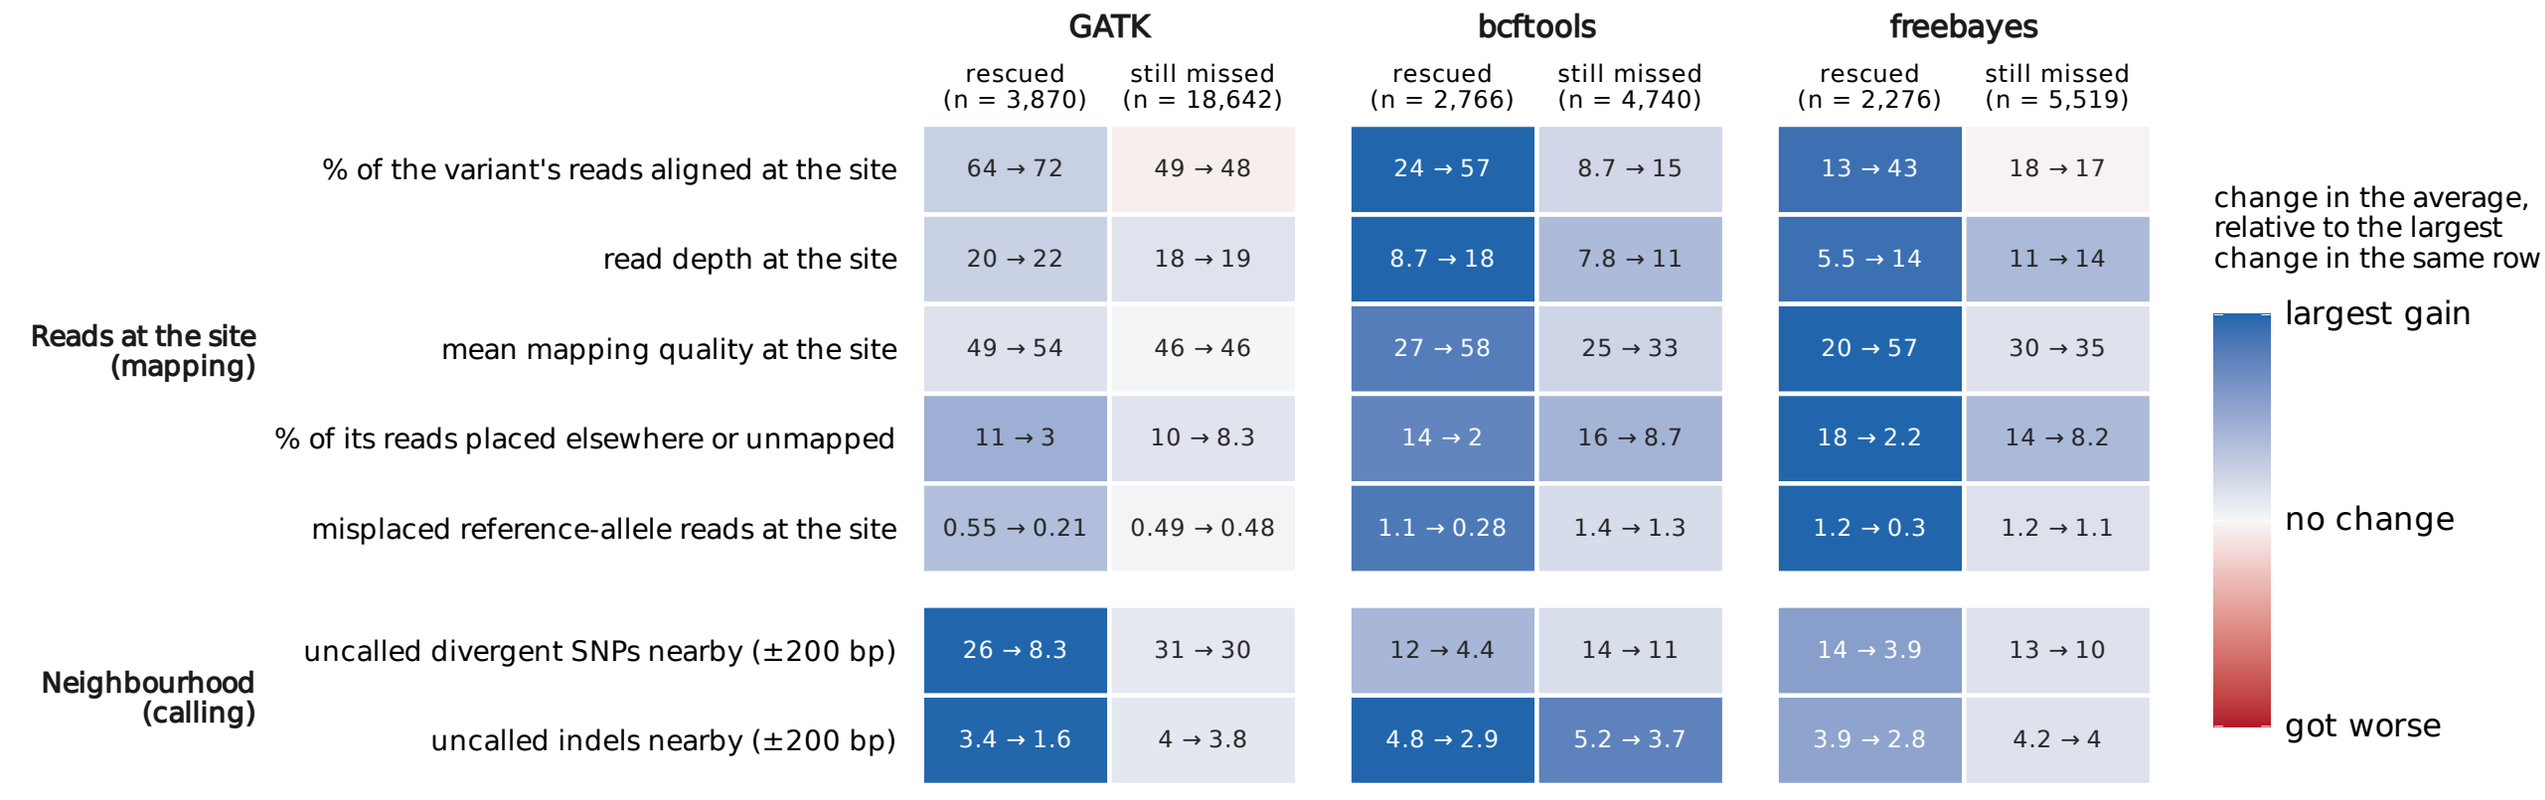
What changed for the SNPs that iteration rescued

SNPs not called in one iteration: those called in the next ('rescued') vs those still not called.
Each cell: average before → after one more iteration; blue = improved.



Data: s02 uniform SNP + indel simulation, D = 0.10; systematic sample of 30,107 divergent SNPs (mason true read origins).
Pairs = the same SNP in consecutive iterations (1 → 2 and 2 → 3 pooled), kept if not called in the earlier one; n = SNP-iteration pairs.
Colour = change in the group average divided by the largest change in that row (rows have different units), signed so blue = better (more reads / higher quality, or fewer misplaced reads / uncalled neighbours).
